ClinicalTrials.gov identifier: NCT02251496
Background

• Malnutrition is common in patients with chronic obstructive pulmonary disease (COPD)
  – ↑complications, ↑hospital stay and ↑mortality
  – leading to an increased economic and operational burden for health services

• Many randomized trials have investigated nutritional interventions to treat malnutrition in stable COPD patients
  – positive impact on survival, rate of complications, length of stay (LOS) and hospital readmissions as well as some nutritional and patient-centered outcomes

• Most of the studies focused on oral nutritional supplements (ONS)
  – often comparing ONS to control group receiving no nutritional intervention

Background

• Few clinical studies and none in COPD patients evaluating the use of energy and protein dense in-between meal snacks alone
  – relatively cheaper approach than ONS
  – increases the variety of options for the patient

• Studies have mainly focused on weight change, mortality, LOS and hospital readmissions as outcomes

• Few have assessed the effect of nutritional support on quality of life
  – outcome particularly relevant to the patient

Aim

The aim of this 12-month randomized intervention trial were:

1) To study the feasibility of the recruitment, retention and provision of each intervention
2) To study the potential impact of the provision of Snacks compared with ONS on body weight and QoL in patients with COPD.

Methods

• Randomized controlled trial
• COPD patients at nutritional risk ≥4 score using a validated screening tool
• Two study groups:
  • ONS or Snacks
• The intervention started in hospital and was continued for 12 months after discharge from the hospital
• Assessments were undertaken in at hospital discharge (baseline) and then at 3, 6, 9 and 12 months post discharge
Outcomes

- **Feasibility outcomes:**
  - percentage of eligible subjects that accepted participation
  - percentage of included subjects that finished the 12 months intervention period
  - use of ONS/Snacks according to 24 hour recalls

- **Primary outcome:**
  - weight change to one year from admission to the hospital
    - bioelectrical impedance analysis (BIA)

- **Secondary outcomes:**
  - quality of life
    - St George’s Respiratory Questionnaire (SGRQ)
  - energy- and protein intake during hospital stay and at home
    - plate diagram sheet and 24 hour recalls
  - lung function (FEV$_1$ and FVC)
    - spirometry
  - functional performance:
    - six-minute walk distance (6MWD)
    - timed up and go (TUG)
    - 30 second chair stand
    - hand-grip strength (HGS)

Results

feasibility outcomes

- Twenty three (68%) of thirty-four participants completed the 12 months study period
- Thirty four (45%) of the 76 eligible patients consented to take part in the study
Mean weight change (%) from baseline

Intention-to-treat analysis. Groups: ONS=oral nutritional supplements, n=16; Snacks, n=13.
Data shown as mean (SD).

Quality of life

Energy- and protein intake/day during hospitalization and in follow up

**Figure 3** a) Energy and b) protein intake/day during hospitalization and in follow up.

Total energy and protein intake per kg actual body weight at baseline, during hospitalization vs. follow up.
ONS 28 kcal vs. 39 kcal, p=0.002 and 1.2 g vs. 1.4 g, p=0.213.

Snacks 32 kcal vs. 40 kcal, p=0.009 and 1.4 g vs. 1.8 g, p=0.048.
Conclusion

• Results from this feasibility study suggest that the provision of Snacks are at least as feasible and effective as ONS to patients with COPD who are at nutritional risk

• Adequately powered RCTs are required to confirm this effect

• Future RCTs should be informed by the recruitment and retention issues that have been raised
